

Efdege® case report from Bolzano Central Hospital, Italy

Fifty-six -year-old female patient with poorly differentiated adenocarcinoma of upper lobe of the right lung performed ^{18}F -FDG (Efdege®) PET scan for staging prior to planned surgery.

The PET/CT scan showed increased Efdege® uptake in the known lung lesion and mediastinal lymph nodes, and furthermore increased Efdege® uptake in bone lesions that had previously not been identified by the CT scan.

Efdege® PET scan is more sensitive than other imaging modalities e.g. CT or a bone scan in detecting bone metastases in patients with lung cancer.

Increased Efdege® uptake in the primary lesion in the right upper lobe, mediastinal lymph nodes and bone lesions.
